40th International Chemistry Olympiad

Theoretical Problems

17 July 2008
Budapest, Hungary

Instructions

- Write your name and code on each page.

- You have 5 hours to work on the problems. Begin only when the START command is given.

- Use only the pen and calculator provided.

- All results **must** be written in the appropriate boxes. Anything written elsewhere will not be graded. Use the reverse of the sheets if you need scratch paper.

- Write relevant calculations in the appropriate boxes when necessary. If you provide only correct end results for complicated problems, you receive no score.

- When you have finished the examination, you must put your papers into the envelope provided. **Do not** seal the envelope.

- You must **stop** your work **immediately when the STOP command is given**. A delay in doing this by 3 minutes may lead to cancellation of your exam.

- **Do not leave** your seat until permitted by the supervisors.

- This examination has **29** pages.

- The official English version of this examination is available on request only for clarification.

Constants and Formulae

Avogadro constant:	$N_A = 6.022 \cdot 10^{23}\ mol^{-1}$	Ideal gas equation: $\quad pV = nRT$
Gas constant:	$R = 8.314\ J\ K^{-1}\ mol^{-1}$	Gibbs energy: $\quad G = H - TS$
Faraday constant:	$F = 96{,}485\ C\ mol^{-1}$	$\Delta_r G^o = -RT \ln K = -nFE^o_{cell}$
Planck constant:	$h = 6.626 \cdot 10^{-34}\ J\ s$	Nernst equation: $\quad E = E^o + \dfrac{RT}{zF} \ln \dfrac{c_{ox}}{c_{red}}$
Speed of light:	$c = 3.000 \cdot 10^{8}\ m\ s^{-1}$	Energy of a photon: $\quad E = \dfrac{hc}{\lambda}$
Zero of the Celsius scale:	$273.15\ K$	Lambert-Beer law: $\quad A = \log \dfrac{I_0}{I} = \varepsilon c l$

In equilibrium constant calculations all concentrations are referenced to a standard concentration of 1 mol/dm³. Assume all gases as ideal throughout the exam.

Problem 1   6% of the total

1a	1b	1c	1d	Task 1
4	2	8	8	22

The label on a bottle containing a dilute aqueous solution of an acid is damaged. Only its concentration could be read. A pH meter was nearby, and a quick measurement on the pH meter showed the hydrogen ion concentration to be equal to the value on the label.

a) <u>Give</u> the formulae of four acids that could have been in the solution if the pH changed one unit after a tenfold dilution.

b) <u>Could</u> it be possible that the dilute solution contained sulfuric acid?

Sulfuric acid: $pK_{a2} = 1.99$

☐ Yes ☐ No

If yes, <u>calculate</u> the pH (or at least try to estimate it) and show your work.

pH:

c) <u>Could</u> it be possible that the solution contained acetic acid?

Acetic acid: $pK_a = 4.76$

☐ Yes ☐ No

If yes, <u>calculate</u> the pH (or at least try to estimate it) and show your work.

pH:

d) <u>Could</u> it be possible that the solution contained EDTA (ethylene diamino tetraacetic acid)? You may use reasonable approximations.

EDTA: $pK_{a1} = 1.70$, $pK_{a2} = 2.60$, $pK_{a3} = 6.30$, $pK_{a4} = 10.60$

☐ Yes ☐ No

If yes, <u>calculate</u> the concentration.

c_{EDTA}:

Problem 2

7% of the total

Task 2
18

<u>Determine</u> the structure of the compounds **A-H** (stereochemistry is not expected), based on the information given in the following reaction scheme:

$$A \xrightarrow[\text{+ 5 H}_2]{\text{Pd}} B (C_{10}H_{18}) \xrightarrow[\text{oxidation}]{\text{radical}} C (C_{10}H_{18}O) \xrightarrow[\text{- H}_2O]{\text{ZnCl}_2} D$$

450°C (A upward arrow)

$$D \xrightarrow[\text{2. Zn/H}^+]{\text{1. O}_3} E$$

$$H \xleftarrow[\text{- H}_2O, - 8 H}]{\text{Pd/C, 350°C}} G \xleftarrow[\text{2. NaBH}_4]{\text{1. Pd/H}_2} F \xleftarrow[\text{- H}_2O}]{\text{Na}_2CO_3, \Delta} E$$
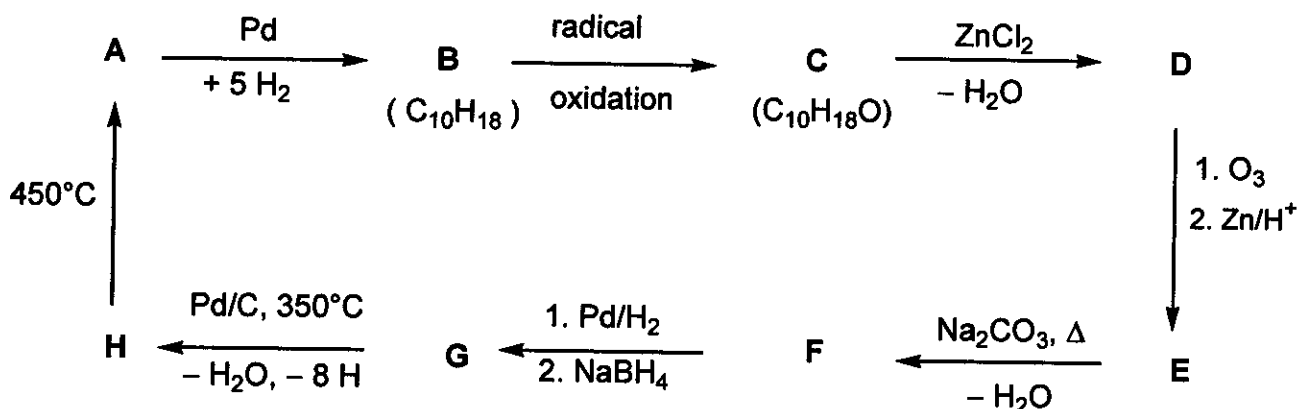

Hints:

- **A** is a well-known aromatic hydrocarbon.

- A hexane solution of **C** reacts with sodium (gas evolution can be observed), but **C** does not react with chromic acid.

- ^{13}C NMR spectroscopy shows that **D** and **E** contain only two kinds of CH_2 groups.

- When a solution of **E** is heated with sodium carbonate an unstable intermediate forms at first, which gives **F** on dehydration.

A	B	C	D
H	G	F	E

3a	3b	3c	Task 3
4	8	2	14

Vinpocetine (Cavinton®, Calan®) is one of the best selling original drugs developed in Hungary. Its preparation relies on a natural precursor, (+)-vincamine ($C_{21}H_{26}N_2O_3$), which is isolated from the vine plant, *vinca minor*. The transformation of (+)-vincamine to vinpocetine (**B**) is achieved in two steps depicted below.

Vincamine

cat. conc. H_2SO_4 / CH_2Cl_2 → **A**

1. NaOH
2. C_2H_5Br / C_2H_5OH → **B** (Vinpocetine)
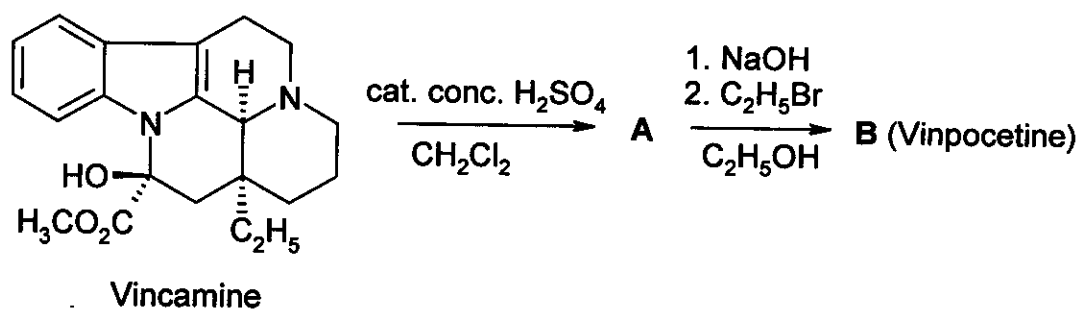

All compounds (**A** to **F**) are enantiomerically pure compounds.

- The elementary composition of **A** is: C 74.97%, H 7.19%, N 8.33%, O 9.55%.
- **B** has 3 other stereoisomers.

a) Propose structures for the intermediate **A** and vinpocetine (**B**).

A	B

Name: Code: MAS-

A study of the metabolism of any drug forms a substantial part of its documentation. There are four major metabolites formed from vinpocetine (**B**): **C** and **D** are formed in hydrolysis or hydration reactions, while **E** and **F** are oxidation products.

Hints:

- The acidity of the metabolites decreases in the order **C** >> **E** >> **D**. **F** does not contain an acidic hydrogen.

- **C** and **E** each have 3 other stereoisomers, while **D** and **F** each have 7 other stereoisomers.

- **F** is a pentacyclic zwitterion and it has the same elementary analysis as **E**: C 72.11%, H 7.15%, N 7.64%, O 13.10%.

- The formation of **E** from **B** follows an electrophilic pattern.

- The formation of **D** from **B** is both regio- and stereoselective.

b) Propose one *possible* structure for each of the metabolites **C**, **D**, **E** and **F**.

C	D
E	F
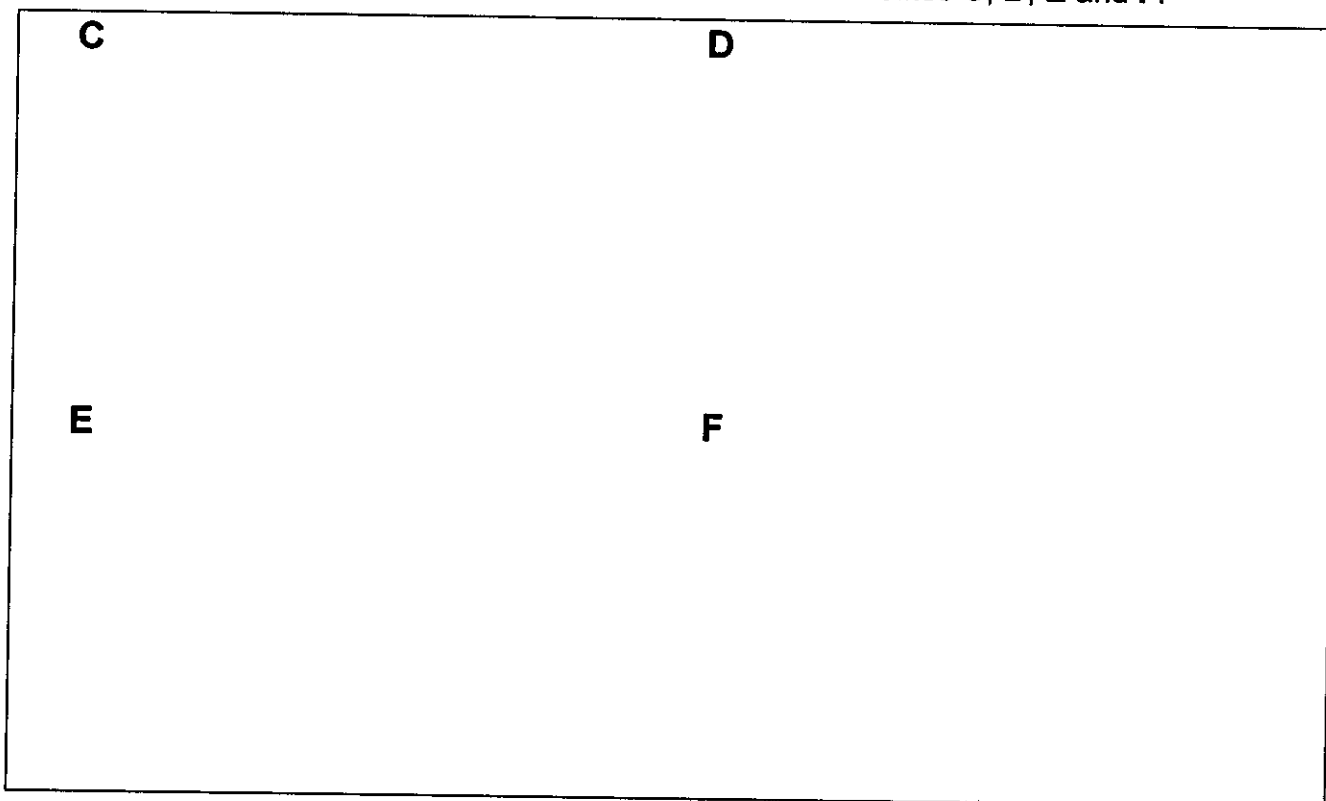

c) Draw a resonance structure for **B** that explains the regioselective formation of **D** and the absence of the alternate regioisomer in particular.
Problem 4   ## 6% of the total

4a	4b	4c	4d	4e	Task 4
6	2	6	8	6	28

A major transformation route for oxiranes (epoxides) is ring opening. This may be accomplished in various ways.

On acid catalysis, the reactions proceed through cation-like (carbenium ion-like) species. For substituted oxiranes the direction of ring opening (in which C–O bond is cleaved) depends on the stability of the intermediate carbenium ion. The more stable the intermediate carbenium ion is, the more probable is its formation. However, an open carbenium ion (with a planar structure) will only form if it is tertiary, benzylic or allylic.

On base catalysis, the sterically less hindered C–O bond is cleaved predominantly.

Keep stereochemistry in mind throughout the whole problem by using only "⬛━ ⸳⸳⸳⸳ⅠⅠⅠ ——— " as bond symbols and nothing else where necessary.

a)   Draw the structures of the starting material and the predominant products when 2,2-dimethyl-oxirane (1,2-epoxy-2-methylpropane) reacts with methanol at low temperatures, catalysed by:

   (i) sulphuric acid
   (ii) $NaOCH_3$.

2,2-dimethyloxirane

   H^+ $NaOCH_3$
   ←————————   ————————→
   CH_3OH CH_3OH

---
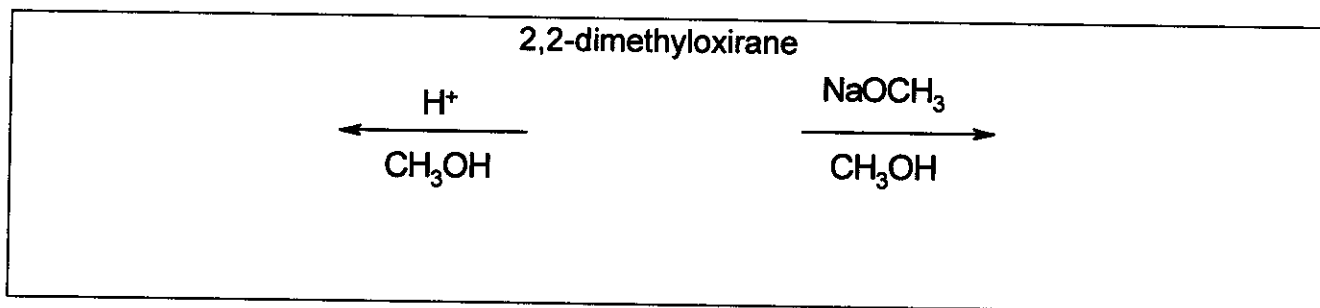

b)   Draw the structure of the predominant product formed when the epoxide ring of the following leukotriene derivative is opened with a thiolate (RS^-).

1. RS^-
2. H^+
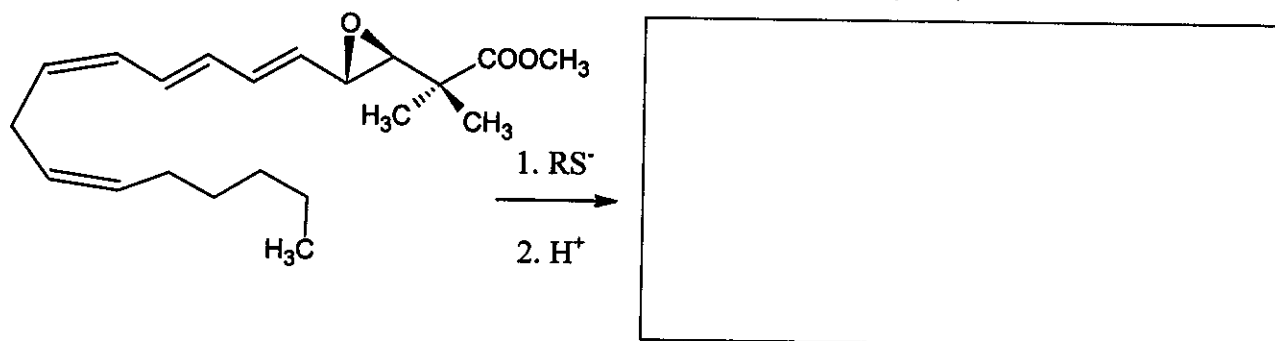

Different porous **acidic** aluminosilicates can also be used to catalyse the transformation of alkyl oxiranes. In addition to ring opening, cyclic dimerisation is found to be the main reaction pathway producing mainly 1,4-dioxane derivatives (six-membered saturated rings with two oxygen atoms in positions 1,4).

c) <u>Draw</u> the structure(s) of the most probable 1,4-dioxane derivative(s) when the starting compound is (S)-2-methyloxirane ((S)-1,2-epoxypropane). <u>Give</u> the structure of the starting material as well.

(S)-2-methyloxirane   **product**
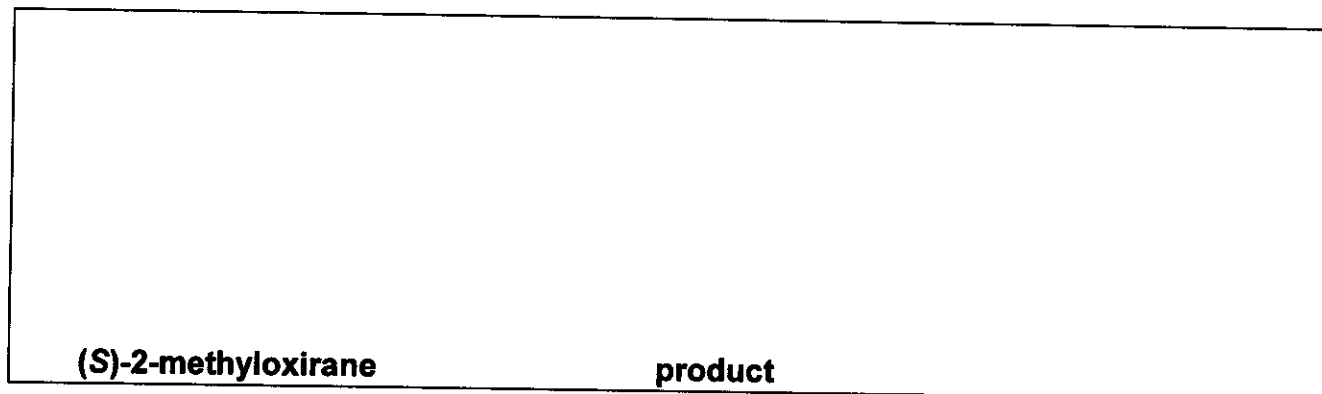

d) <u>Draw</u> the structure(s) of the substituted 1,4-dioxane(s) when the epoxide reacting is (R)-1,2-epoxy-2-methylbutane ((R)-2-ethyl-2-methyloxirane). <u>Give</u> the structure of the starting material as well.

(R)-1,2-epoxy-2-methylbutane:
Product(s):

e) <u>Give</u> the structure(s) of the substituted 1,4-dioxane(s) when this reaction is carried out with racemic 1,2-epoxy-2-methylbutane (2-ethyl-2-methyloxirane).

Product(s):

5a	5b	Task 5
67	33	100

A and B are white crystalline substances. Both are highly soluble in water and can be moderately heated (up to 200 °C) without change. However both decompose at higher temperatures.

If an aqueous solution of 20.00 g A (which is slightly basic, pH ≈ 8.5-9) is added to an aqueous solution of 11.52 g B (which is slightly acidic, pH ≈ 4.5-5), a white precipitate C is formed. The precipitate C weighs 20.35 g after filtering, washing and drying.

The filtrate is essentially neutral and when reacted with an acidified KI solution, it gives a brown colour solution. When boiled, the filtrate evaporates without the appearance of any residue.

The white solid D can be prepared by heating A in the absence of air.

The exothermic reaction of D with water gives a colourless solution.

This solution, if kept in an open container, slowly gives a white solid precipitate E and water.

Upon prolonged exposure to air at room temperature, solid D is transformed into E as well.

However, heating D in air at 500 °C produces a different white substance F. F is barely soluble in water and has a mass of only 85.8% of the E formed from the same amount of D.

F gives a brown colour reaction with an acidified solution of KI.

E can be converted back into D but ignition above 1400 °C is required for this purpose.

The reaction of B and D in water forms the precipitate C and is accompanied by a characteristic odour.

a)   Give the formulae of the substances A - F

A	B	C
D	E	F

b) <u>Write</u> balanced equations for **all the reactions mentioned**. (The equation for the thermal decomposition of **B** is not required.)

Equations:

Problem 6   # 7% of the total

6a	6b	6c	6d	6e	6f	6g	Task 6

A feathery, greenish solid precipitate can be observed if chlorine gas is bubbled into water close to its freezing point. Similar precipitates form with other gases such as methane and noble gases. These materials are interesting because vast quantities of the so-called methane hydrates are supposed to exist in nature (comparable in quantity with other natural gas deposits).

These precipitates all have related structures. The molecules of water just above its freezing point form a hydrogen-bonded structure. The gas molecules stabilize this framework by filling in the rather large cavities within the water structure, forming clathrates.

The crystals of chlorine and methane clathrates have the same structure. The lattice points of the unit cell consist of dodecahedra (formed from 20 water molecules). The unit cell can be thought of as a body-centered cubic arrangement built from these dodecahedra which are almost spherical objects. The dodecahedra within the unit cell are connected via additional water molecules located on the faces of the unit cell. Two water molecules can be found on each face of the unit cell. The unit cell has an edge dimension of 1.182 nm.

There are two types of cavities in this structure. One is the internal space in the dodecahedra (**A**). These are somewhat smaller than the other type of voids (**B**), of which there are 6 for each unit cell.

a) How many type **A** cavities can be found in a unit cell?

b) How many water molecules are there in a unit cell?

c) If all cavities contain a guest molecule, what is the ratio of the number of water to the number of guest molecules?

d) Methane hydrate is formed with the structure in **c)** at temperatures between 0-10 °C. <u>What</u> is the density of the clathrate?

Density:

e) The density of chlorine hydrate is 1.26 g/cm^3. <u>What</u> is the ratio of the number of water to the number of guest molecules in the crystal?

Ratio:

<u>Which</u> cavities are likely to be filled in a perfect chlorine hydrate crystal? Mark one or more.

☐ Some **A**   ☐ Some **B**   ☐ All **A**   ☐ All **B**

Covalent radii reflect atomic distances when the atoms are covalently bonded.

Non-bonded or van der Waals radii give a measure of the atomic size when they are not bonded covalently (modeled as hard spheres).

Atom	Covalent radius (pm)	Non-bonded radius (pm)
H	37	120
C	77	185
O	73	140
Cl	99	180

f) Based on the covalent and nonbonded radii of these atoms, <u>estimate</u> the possible lower and upper bounds of the average radii for the cavities. <u>Show</u> your reasoning.

$< r(A) <$ $< r(B)$

Let us consider the following processes:

$$H_2O(l) \rightarrow H_2O(s) \qquad\qquad (1)$$

$$x\,CH_4(g) + H_2O\,(l) \rightarrow xCH_4.1H_2O(\text{clathrate}) \qquad (2)$$

g) <u>What</u> are the signs of the following molar quantities referring to these reactions (in the given direction) at 4 °C? <u>Mark</u> with a "–", "0" or "+".

	sign
$\Delta G_m(1)$	
$\Delta G_m(2)$	
$\Delta H_m(1)$	
$\Delta H_m(2)$	
$\Delta S_m(1)$	
$\Delta S_m(2)$	
$\Delta S_m(2) - \Delta S_m(1)$	
$\Delta H_m(2) - \Delta H_m(1)$	

Problem 7   8% of the total

2	1	4	2	8	5	8	12	42

The dithionate ion ($S_2O_6^{2-}$) is a rather inert inorganic ion. It can be prepared by bubbling sulphur-dioxide continously into ice-cooled water to which manganese dioxide is added in small increments. Dithionate and sulphate ions are formed under these circumstances.

a) Write the balanced chemical equations for the two reactions.

After the reaction is completed, $Ba(OH)_2$ is added to the mixture until the sulphate ions are fully precipitated. This is followed by the addition of Na_2CO_3.

b) Write the balanced equation for the reaction that takes place upon the addition of Na_2CO_3.

Sodium dithionate is then crystallized by evaporating some of the solvent. The prepared crystals dissolve readily in water but do not give a precipitate with $BaCl_2$ solution. When the solid is heated and maintained at 130 °C, 14.88 % weight loss is observed. The resulting white powder dissolves in water but does not give a precipitate with $BaCl_2$ solution.

When another sample of the original crystals is kept at 300 °C for a few hours, 41.34 % weight loss occured. The resulting white powder dissolves in water and gives a white precipitate with $BaCl_2$ solution.

c) Give the composition of the prepared crystals and write balanced equations for the two processes that occur during heating.

Formula:

Equation (130 °C):

Equation (300 °C):

Although dithionate ion is a fairly good reducing agent thermodynamically, it does not react with oxidants in solution at room temperature. At 75 °C, however, it can be oxidized in acidic solutions. A series of kinetic experiments were carried out with bromine as the oxidant.

d) Write the balanced chemical equation for the reaction between bromine and dithionate ion.

The initial rates (v_0) of the reaction were determined in a number of experiments at 75 °C.

$[Br_2]_0$ (mmol/dm³)	$[Na_2S_2O_6]_0$ (mol/dm³)	$[H^+]_0$ (mol/dm³)	v_0 (nmol dm⁻³s⁻¹)

e) Determine the order of the reaction with respect to Br_2, H^+ and $S_2O_6^{2-}$, the experimental rate equation, and the value and unit of the rate constant.

The order for the reaction: Br_2:   for H^+:   for $S_2O_6^{2-}$:

Experimental rate equation:

k:

In similar experiments, chlorine, bromate ion, hydrogen peroxide and chromate ion have all been used as oxidizing agents at 75 °C. The rate equations for these processes are analogous to the one observed with bromine, the units of all rate constants are the same, their values are $2.53 \cdot 10^{-5}$ (Cl_2), $2.60 \cdot 10^{-5}$ (BrO_3^-), $2.56 \cdot 10^{-5}$ (H_2O_2), and $2.54 \cdot 10^{-5}$ ($Cr_2O_7^{2-}$).

Experiments were also carried out in acidic sodium dithionate solution without any oxidizing agent. Following the processes by UV spectrophotometry showed a slow appearance of a new absorption band around 275 nm. Although hydrogen sulphate ion is a detectable product of the reaction, it does not absorb any light above 200 nm.

f)   Give the formula of the major species causing this new absorption band and write the balanced equation for the chemical reaction occurring in the absence of oxidants.

Species:

Reaction:

An experiment was carried out to follow the absorbance at 275 nm with initial concentrations: $[Na_2S_2O_6]$ = 0.0022 mol/dm^3, $[H^+]$ = 0.70 mol/dm^3 at 75 °C. A pseudo first-order kinetic curve was found with a half-life of 10 hours and 45 minutes.

g)   Calculate the rate constant of the reaction.

k:

Suggest a balanced chemical equation for the rate determining step of the reactions that used an oxidizing agent.

Rate determining step:

When periodate ion (which is present as $H_4IO_6^-$ in aqueous solution) was used as an oxidant for dithionate ion, the two kinetic curves depicted in the graph below were detected at 75 °C in the same experiment at two different wavelengths. The initial concentrations were $[H_4IO_6^-] = 5.3 \cdot 10^{-4}$ mol/dm^3, $[Na_2S_2O_6] = 0.0519$ mol/dm^3, $[H^+] = 0.728$ mol/dm^3

At 465 nm, only I_2 absorbs and its molar absorption coefficient is 715 dm^{3}mol^{-1}cm^{-1}. At 350 nm, only I_3^- absorbs and its molar absorption coefficient is 11,000 dm^{3}mol^{-1}cm^{-1}. The optical path length was 0.874 cm.
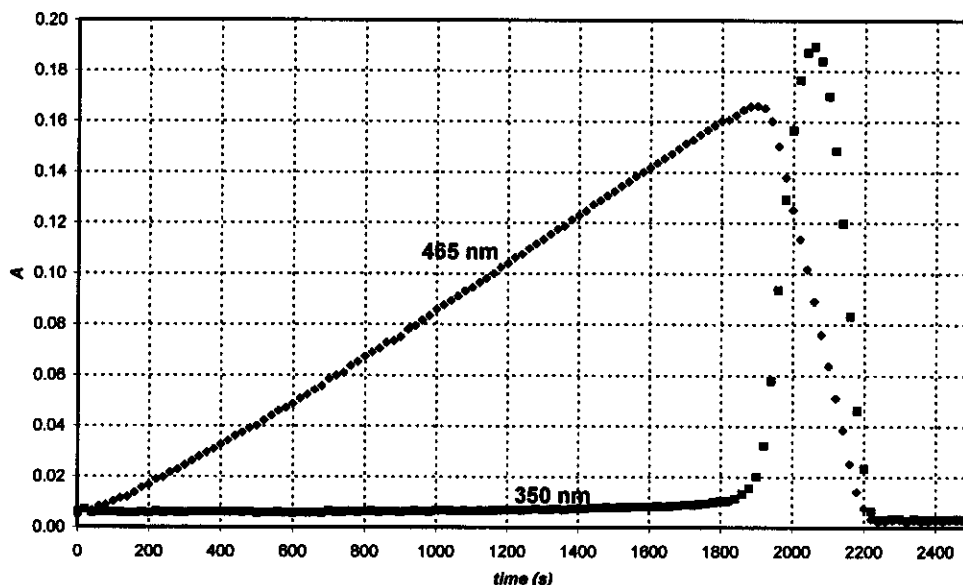

h)   Write balanced chemical equations for the reactions that occur in the region where the absorbance increases at 465 nm, and in the region where the absorbance decreases at 465 nm.

Increase:

Decrease:

Calculate the expected time for the maximum absorbance of the kinetic curve measured at 465 nm.

t_{max}:

Estimate the expected ratio of the slopes of the increasing and decreasing regions in the kinetic curve measured at 465 nm

Slope ratio:

8a	8b	8c	8d	8e	8f	8g	8h	8i	Task 8
3	3	4	3	3	2	7	3	5	32

Ms. Z was a bright student whose research project was to measure the complexation of all lanthanide(III) ions with newly designed complexing ligands. One day she monitored the UV-Vis absorption with Ce(III) and a particularly poor complexing ligand in a spectrophotometer. She noticed that some small bubbles had formed in the closed cell by the end of the 12-hour experiment.

Soon she realized that the presence of the ligand is not necessary to see the bubble formation, and continued her experiments with an acidified $CeCl_3$ solution. Bubble formation never occurred when she just kept the solution in the spectrophotometer without turning on the instrument.

Next, Ms. Z used a small quartz flask, in which she could dip a chloride ion selective electrode and also withdraw samples regularly for spectrophotometric measurements. She calibrated the chloride ion selective electrode using two different NaCl solutions and obtained the following results:

c_{NaCl} (mol/dm^3)	E (mV)
0.1000	26.9
1.000	-32.2

a) Give a formula to calculate the chloride ion concentration of an unknown sample based on the electrode voltage reading (E).

[Cl⁻] =

Ms. Z also determined the molar absorption coefficient for Ce^{3+} (ε = 35.2 dm^{3}mol^{-1}cm^{-1}) at 295 nm, and, as a precaution, also for Ce^{4+} (ε = 3967 dm^{3}mol^{-1}cm^{-1}).

b) Give a formula to calculate the Ce^{3+} concentration from an absorbance reading at 295 nm (A) measured in a solution containing $CeCl_3$ (cuvette path length: 1.000 cm).

[Ce³⁺] =

Ms. Z prepared a solution which contained 0.0100 mol dm^{-3} $CeCl_3$ and 0.1050 mol dm^{-3} HCl, and began her experiment by turning on the quartz lamp. HCl does not absorb at 295 nm.

c) <u>What</u> were the expected initial absorbance and voltage readings?

$A_{295nm}=$

$E =$

Before the quantitative experiment, Ms. Z collected the gas formed into a carefully neutralized solution of methyl orange (acid-base and redox indicator). Although she saw bubbles going through the solution, the colour did not change or fade even after a day.

d) <u>Give</u> the formula of two gases, comprised of elements in the illuminated sample, which could not be present given the results of this experiment.

During her quantitative experiment she recorded the absorbance and voltage values regularly. The uncertainty of the spectophotometric measurements is ±0.002 and the accuracy of the voltage measurements is ±0.3 mV.

time (min)	0	120	240	360	480
$A_{295\ nm}$	0.3496	0.3488	0.3504	0.3489	0.3499
E (mV)	19.0	18.8	18.8	19.1	19.2

e) Estimate the average rate of change in the concentrations of Ce^{3+}, Cl^-, and H^+.

$d[Ce^{3+}]/dt =$

$d[Cl^-]/dt =$

$d[H^+]/dt =$

Name: Code: MAS-

The following day, Ms. Z used an intense monochromatic light beam (254 nm) with an intensity of 0.0500 W. She passed this light through a 5-cm long quartz photoreactor filled with the same acidic $CeCl_3$ solution she had used before. She measured the molar absorption coefficient for Ce^{3+} ($\varepsilon = 2400$ $dm^3 mol^{-1} cm^{-1}$) at 254 nm.

f) <u>What</u> percentage of the light is absorbed in this experiment?

The equipment allowed her to lead the gas first through a drying tube that removed traces of water vapour and then into a closed chamber, whose volume was 68 cm^3. The chamber was equipped with a high-precision manometer and an igniter. She first filled the chamber with dry argon to a pressure of 102,165 Pa and then she turned on the lamp. In 18.00 hours, the pressure reached 114,075 Pa. The temperature of the equipment was 22.0 °C.

g) <u>Calculate</u> the amount of substance of the gas collected in the chamber.

n_{gas}:

At this point, Ms. Z turned off the light and pressed the ignition button. When the chamber cooled to the initial temperature, the final pressure was 104,740 Pa.

<u>Suggest</u> the formula(s) of the gas(es) formed and collected, and <u>**give**</u> the balanced equation for the original chemical reaction taking place under illumination.

Gas(es):

Reaction:

h) <u>What</u> would be the final pressure after the ignition, if the chamber was filled for 24 hours before ignition?

$p =$

i) <u>Calculate</u> the quantum yield of product formed in the Ce(III) solution.
Quantum yield:

Name:

Problem 9   6 % of the total

9a	9b	9c	9d	Task 9
12	21	15	9	57

Thallium exists in two different oxidation states: Tl^+ and Tl^{3+}.
Iodide ions can combine with iodine to form tri-iodide ions (I_3^-) in aqueous solutions.

The standard redox potentials for some relevant reactions are:

$$Tl^+(aq) + e^- \rightarrow Tl(s) \qquad E^0_1 = -0.336 \text{ V}$$
$$Tl^{3+}(aq) + 3e^- \rightarrow Tl(s) \qquad E^0_2 = +0.728 \text{ V}$$
$$I_2(s) + 2e^- \rightleftharpoons 2I^-(aq) \qquad E^0_3 = +0.540 \text{ V}$$

The equilibrium constant for the reaction $I_2(s) + I^-(aq) \rightarrow I_3^-(aq)$ is $K_1 = 0.459$.

Use $T=25\ °C$ throughout this problem.

a)   Calculate the redox potential for the following reactions:

$$Tl^{3+}(aq) + 2\ e^- \rightarrow Tl^+(aq) \qquad E^0_4$$

$E^0_4 =$

$$I_3^-(aq) + 2\ e^- \rightarrow 3\ I^-(aq) \qquad E^0_5$$

$E^0_5 =$

---
b) Write the empirical formulae for **all** theoretically possible neutral compounds that contain one thallium ion and any combination of iodide and/or tri-iodide ion(s) as anion(s).

There is an empirical formula that could belong to two different compounds. Which one?

Based on the standard redox potentials, **which** of the two isomers mentioned above is the stable one at standard conditions?

Write the chemical reaction for the isomerisation of the other isomer of thallium iodide.

More stable isomer:

Isomerisation:

Complex formation can shift this equilibrium. The cumulative complex formation constant for the reaction $Tl^{3+} + 4I^- \rightarrow TlI_4^-$ is $\beta_4 = 10^{35.7}$

c) **Write** the reaction that takes place when a solution of the more stable isomer of thallium iodide is treated with an excess of KI. **Calculate** the equilibrium constant for this reaction.

Reaction:

K_2:

If the solution of the more stable isomer is treated with a strong basic reagent, precipitation of a black substance can be observed. After the water content of the precipitate is removed, the remaining material contains 89.5% thallium (by mass).

d) **What** is the empirical formula of this compound? Show your calculations. **Write** a balanced equation for its formation.

Formula:

Equation:
